15 — Abstract —

16 Multiple inheritance is a valuable feature for Object-Oriented Programming. However, it is also
17 tricky to get right, as illustrated by the extensive literature on the topic. A key issue is the *am-*
18 *biguity* arising from inheriting multiple parents, which can have conflicting methods. Numerous
19 existing work provides solutions for conflicts which arise from *diamond inheritance*: i.e. conflicts
20 that arise from implementations sharing a common ancestor. However, most mechanisms are
21 inadequate to deal with *unintentional method conflicts*: conflicts which arise from two unrelated
22 methods that happen to share the same name and signature.

23 This paper presents a new model called *Featherweight Hierarchical Java* (**FHJ**) that deals
24 with unintentional method conflicts. In our new model, which is partly inspired by C++, con-
25 flicting methods arising from unrelated methods can coexist in the same class, and *hierarchical*
26 *dispatching* supports unambiguous lookups in the presence of such conflicting methods. To avoid
27 ambiguity, hierarchical information is employed in method dispatching, which uses a combination
28 of static and dynamic type information to choose the implementation of a method at run-time.
29 Furthermore, unlike all existing inheritance models, our model supports *hierarchical method*
30 *overriding*: that is, methods can be *independently overridden* along the multiple inheritance hi-
31 erarchy. We give illustrative examples of our language and features and formalize **FHJ** as a
32 minimal Featherweight-Java style calculus.

1 Introduction

Inheritance in Object-Oriented Programming (OOP) offers a mechanism for code reuse. However many OOP languages are restricted to single inheritance, which is less expressive and flexible than multiple inheritance. Nevertheless, different flavours of multiple inheritance have been adopted in some popular OOP languages. C++ has had multiple inheritance from the start. Scala adapts the ideas from traits [28, 9, 16] and mixins [5, 11, 32, 2, 13] to offer a disciplined form of multiple inheritance. Java 8 offers a simple variant of traits, disguised as interfaces with default methods [12].

A reason why programming languages have resisted to multiple inheritance in the past is that, as Cook [7] puts it, “*multiple inheritance is good but there is no good way to do it*”. One of the most sensitive and critical issues is perhaps the ambiguity introduced by multiple inheritance. One case is the famous *diamond problem* [27, 29] (also known as *fork-join inheritance* [27]). In the diamond problem, inheritance allows one feature to be inherited from multiple parent classes that share a common ancestor. Hence conflicts arise. The variety of strategies for resolving such conflicts urges the occurrence of different multiple inheritance models, including traits, mixins, CZ [17], and many others. Existing languages and research have addressed the issue of diamond inheritance extensively. Other issues including how multiple inheritance deals with state, have also been discussed quite extensively [33, 17, 31].

In contrast to diamond inheritance, the second case of ambiguity is *unintentional method conflicts* [28]. In this case, conflicting methods do not actually refer to the same feature. In a nominal system, methods can be designed for different functionality, but happen to have the same names (and signatures). A simple example of this situation is two `draw` methods that are inherited from a deck of cards and a drawable widget, respectively. In such context, the two `draw` methods have very different meanings, but they happen to share the same name. When inheritance is used to compose these classes, a compilation error happens due to conflicts. However, unlike the diamond problem, the conflicting methods have very different meanings and do not share a common parent. We call such a case *fork inheritance*, in analogy to diamond inheritance.

When unintentional method conflicts happen, they can have severe effects in practice if no appropriate mechanisms to deal with them are available. In practice, existing languages only provide limited support for the issue. In most languages, the mechanisms available to deal with this problem are the same as the diamond inheritance. However, this is often inadequate and can lead to tricky problems in practice. This is especially the case when it is necessary to combine two large modules and their features, but the inheritance is simply prohibited by a small conflict. As a workaround from the diamond inheritance side, it is possible to define a new method in the child class to override those conflicting methods. However, using one method to fuse two unrelated features is clearly unsatisfactory. Therefore we need a better solution to keep both features separately during inheritance, so as not to break *independent extensibility* [36].

C++ and C# do allow for two unintentionally conflicting methods to coexist in a class. C# allows this by interface multiple inheritance and explicit method implementations. But since C# is a single inheritance language, it is only possible to *implement* multiple interfaces (but not multiple classes). C++ accepts fork inheritance and resolves the ambiguity by specifying the expected path by *upcasts*. However, neither the C# nor C++ approaches allow such conflicting methods to be further overridden. Some other workarounds or approaches include delegation and renaming/exclusion in the trait model. However, renaming/exclusion can break the subtyping relation between a subclass and its parent. This is not adequate for

■ **Figure 1** DrawableSafeDeck: an illustration of hierarchical overriding.

the class model commonly used in mainstream OOP languages, where the subclass is always expected to be a subtype of the parent class.

This paper proposes two mechanisms to deal with unintentional method conflicts: *hierarchical dispatching* and *hierarchical overriding*. Hierarchical dispatching is inspired by the mechanisms in C++ and provides an approach to method dispatching, which combines static and dynamic information. Using hierarchical dispatching, the method binder will look at both the *static type* and the *dynamic type* of the receiver during runtime. When there are multiple branches that cause unintentional conflicts, the static type can specify one branch among them for unambiguity, and the dynamic type helps to find the most specific implementation. In that case, both unambiguity and extensibility are preserved. The main novelty over existing work is the formalization of the essence of a hierarchical dispatching algorithm, which (as far as we know) has not been formalized before.

Hierarchical overriding is a novel language mechanism that allows method overriding to be applied only to one branch of the class hierarchy. Hierarchical overriding adds expressive power that is not available in languages such as C++ or C#. Hierarchical overriding allows overriding to work for classes with multiple (conflicting) methods sharing the same names and signatures. An example is presented in Figure 1. In this example, there are 4 classes/interfaces. Two classes `Deck` and `Drawable` model a deck of cards and a drawable widget, respectively. The class `SafeDeck` adds functionality to check whether the deck is empty so as to prevent drawing a card from an empty deck. The interesting class is `DrawableSafeDeck`, which inherits from both `SafeDeck` and `Drawable`. Hierarchical overriding is used in `DrawableSafeDeck` to keep two separate `draw` methods for each parent, but override *only* the `draw` method coming from `Drawable`, in order to draw a widget with a deck of cards. Note that hierarchical overriding is denoted in the UML diagram with the notation `draw()↑Drawable`, expressing that the `draw` method from `Drawable` is overridden. Although in this example only one of the `draw` methods is overridden (and the other is simply inherited), hierarchical overriding supports multiple conflicting methods to be independently overridden as well.

To present hierarchical overriding and dispatching, we introduce a formalized model **FHJ** in Section 3 based on Featherweight Java [14], together with theorems and proofs for type soundness. We also have a prototype implementation of a **FHJ** interpreter written in Scala. The implementation validates all the examples presented in the paper. One nice feature of the implementation is that it can show the detailed step-by-step evaluation of the program, which is convenient for understanding and debugging programs & semantics.

In summary, our contributions are:

- **A formalization of the hierarchical dispatching algorithm** that integrates both the static type and dynamic type for method dispatch, and ensures unambiguity as well

- as extensibility in the presence of unintentional method conflicts.
- **Hierarchical overriding**: a novel notion that allows methods to override individual branches of the class hierarchy.
- **FHJ**: a formalized model based on Featherweight Java, supporting the above features. We provide the static and dynamic semantics and prove the type soundness of the model.
- **Prototype implementation**²: a simple implementation of **FHJ** interpreter in Scala. The implementation can type-check and run variants of all the examples shown in this paper.

2 A Running Example: Drawable Deck

This section illustrates the problem of unintentional method conflicts, together with the features of our model for addressing this issue, by a simple running example. In the following text we will introduce three problems one by one and have a discussion on possible workarounds and our solutions. Problems 1 and 2 are related to hierarchical dispatching, and in C++ it is possible to have similar solutions to both problems. Hence it is important to emphasize that, with respect to hierarchical dispatching, our model is not a novel mechanism. Instead, inspired by the C++ solutions, our contribution is formalizing a minimal calculus of this feature together with a proof of type soundness. However, for the final problem, there is no satisfactory approach in existing languages, thus what we propose is a novel feature (hierarchical overriding) with the corresponding formalization of that feature.

In the rest of the paper, we use a Java-like syntax for programs. All types are defined with the keyword **interface**; the concept is closely related to Java 8 interfaces with default methods [4] and traits. In short, an interface in our model has the following characteristics:

- It allows multiple inheritance.
- Every method is either abstract or implemented with a body (like Java 8 default methods).
- The **new** keyword is used to instantiate an interface.
- It cannot have state.

2.1 Problem 1: Basic Unintentional Method Conflicts

Suppose that two components `Deck` and `Drawable` have been developed in a system. `Deck` represents a deck of cards and defines a method `draw` for drawing a card from the deck. `Drawable` is an interface for graphics that can be drawn and also includes a method called `draw` for visual display. For simple illustration, the default implementation of `draw` in `Drawable` only creates a blank canvas on the screen, while the `draw` method in `Deck` simply prints out a message "Draw a card."

```

interface Deck {
    void draw() { // draws a card from the Deck
        println("Draw a card.");
    }
}

interface Drawable {
    void draw() { // create a blank canvas
        JFrame frame = new JFrame();
        frame.setVisible(true);
    }
}

```

² The implementation is available at <https://github.com/YanlinWang/MIM/tree/master/Calculus>

164 }
165

166 In `Deck`, `draw` uses `println`, which is a library function. The two `draw` methods can have
167 different return types, but for simplicity, the return types are both **void** here. Note that,
168 similarly to Featherweight Java [14], **void** is unsupported in our formalization. We could have
169 also defined an interface called `Void` and return an object of that type instead. To be concise,
170 however, we use **void** in our examples. In interface `Drawable`, the `draw` method creates a blank
171 canvas.

172 Now, suppose that a programmer is designing a card game with a GUI. He may want to
173 draw a deck on the screen, so he first defines a drawable deck using multiple inheritance:

174 **interface** `DrawableDeck` **extends** `Drawable`, `Deck` {}
175
176

177 The point of using multiple inheritance is to compose the features from various components
178 and to achieve code reuse, as supported by many mainstream OO languages. Nevertheless,
179 at this point, languages like Java simply treat the two `draw` methods as the same, hence the
180 compiler fails to compile the program and reports an error.

181 This case is an example of a so-called *unintentional method conflict*. It arises when two
182 inherited methods happen to have the same name and parameter types, but they are designed
183 for different functionalities with different semantics. Now one may quickly come up with a
184 workaround, which is to manually merge the two methods by creating a new `draw` method in
185 `DrawableDeck` to override the old ones. However, merging two methods with totally different
186 functionalities does not make any sense. This non-solution would hide the old methods and
187 break independent extensibility.

188 2.1.1 Problem and Possible Workarounds

189 The essential problem is how to resolve unintentional method conflicts and invoke the
190 conflicting methods separately without ambiguity. To tackle this problem, there are several
191 other workarounds that come to our mind. We briefly discuss those potential fixes and
192 workarounds next:

- 193 ■ *I. Delegation.* As an alternative to multiple inheritance, delegation can be used by
194 introducing two fields (or field methods) with the `Drawable` type and `Deck` type, respectively.
195 Although it avoids method conflicts, it is known that using delegation makes it hard to
196 correctly maintain self-references in an extensible system and also introduces a lot of
197 boilerplate code.
- 198 ■ *II. Refactor `Drawable` and/or `Deck` to rename the methods.* If the source code for `Drawable` or
199 `Deck` is available then it may be possible to rename one of the `draw` methods. However this
200 approach is non-modular, as it requires modifying existing code and becomes impossible
201 if the code is unavailable.
- 202 ■ *III. Method exclusion/renaming.* Eiffel [18] and some trait models support method
203 exclusion/renaming. Those features can eliminate conflicts, although most programming
204 languages do not support them. In a traditional OO system, they can break the subtyping
205 relationship. Moreover, in contrast with exclusion, renaming can indeed preserve both
206 conflicting behaviours. However, it is cumbersome in practice, as introducing new names
207 can affect other code blocks.

2.1.2 FHJ's solution

To solve this problem it is important to preserve both conflicting methods during inheritance instead of merging them into a single method. Therefore **FHJ** accepts the definition of **DrawableDeck**. To disambiguate method calls, we can use *upcasts* in **FHJ** to specify the “branch” in the inheritance hierarchy that should be called. The following code illustrates the use of upcasts for disambiguation:

```

214 interface Deck { void draw() {...} }
215 interface Drawable { void draw() {...} }
216 interface DrawableDeck extends Drawable, Deck {}
217 // main program
218 ((Deck) new DrawableDeck()).draw() // calls Deck.draw
219 // new DrawableDeck().draw() // this call is ambiguous and rejected
220

```

YANLIN: Refined. In our language, a program consists of interfaces declarations and a main expression which produces the final result. In the above main expression `((Deck)new DrawableDeck()).draw()`, the cast indicates that we expect to invoke the `draw` method from the branch `Deck`. Similarly, we could have used an upcast to `Drawable` to call the `draw` method from `Drawable`. Without the cast, the call would be ambiguous and **FHJ**'s type system would reject it.

This example illustrates the basic form of fork inheritance, where two unintentionally conflicting methods are accepted by multiple inheritance. Note that C++ supports this feature and also addresses the ambiguity by upcasts. The code for the above example in C++ is similar.

2.2 Problem 2: Dynamic Dispatching

Using explicit upcasts for disambiguation helps when making calls to classes with conflicting methods, but things become more complicated with dynamic dispatching. Dynamic dispatching is very common in OO programming for code reuse. Let us expand the previous example a bit, by redefining those interfaces with more features:

```

237 interface Deck {
238   void draw() {...}
239   void shuffle() {...}
240   void shuffleAndDraw() { this.shuffle(); this.draw(); }
241 }
242

```

Here `shuffleAndDraw` invokes `draw` from its own enclosing type. In **FHJ**, this invocation is dynamically dispatched. This is important, because a programmer may define a subtype of `Deck` and override the method `draw`:

```

247 interface SafeDeck extends Deck {
248   boolean isEmpty() {...}
249   void draw() { // overriding
250     if (isEmpty()) println("The deck is empty.");
251     else println("Draw a card");
252   }
253 }
254

```

Without dynamic dispatching, we may have to copy the `shuffleAndDraw` code into `SafeDeck`, so that `shuffleAndDraw` calls the new `draw` defined in `SafeDeck`. Dynamic dispatching immediately saves us from the duplication work, since the method becomes automatically dispatched to the most specific one. Nevertheless, as seen before, dynamic dispatch would potentially introduce ambiguity. For instance, when we have the class hierarchy structure shown in

■ **Figure 2** UML diagrams for 3 variants of DrawableSafeDeck.

Figure 2(left) with the following code:

```

261
262
263 interface DrawableSafeDeck extends Drawable, SafeDeck {}
264 // main program
265 new DrawableSafeDeck().shuffleAndDraw()
266

```

Indeed, using reduction steps following the reduction rules in FJ [14]-like languages, where no static types are tracked, the reduction steps would roughly be:

```

267
268
269   new DrawableSafeDeck().shuffleAndDraw()
270   -> new DrawableSafeDeck().shuffle(); new DrawableSafeDeck().draw()
271   -> ...
272   -> new DrawableSafeDeck().draw()
273   -> <<error: ambiguous call!!!>>
274
275

```

When the DrawableSafeDeck object calls shuffleAndDraw, the implementation in Deck is dispatched. But then shuffleAndDraw invokes “this.draw()”, and at this point, the receiver is replaced by the object **new** DrawableSafeDeck(). From the perspective of DrawableSafeDeck, the draw method seems to be ambiguous since DrawableSafeDeck inherits two draw methods from both SafeDeck and Drawable. But ideally we would like shuffleAndDraw to invoke SafeDeck.draw because they belong to the same class hierarchy branch.

2.2.1 FHJ’s solution

The essential problem is how to ensure that the correct method is invoked. To solve this problem, **FHJ** uses a variant of method dispatching that we call *hierarchical dispatching*. In hierarchical dispatching, both the static and dynamic type information are used to select the right method implementation. During runtime, a method call makes use of both the static type and the dynamic type of the receiver, so it is a combination of static and dynamic dispatching. Intuitively, the static type specifies one branch to avoid ambiguity, and the dynamic type finds the most specific implementation on that branch. To be specific, the following code is accepted by **FHJ**:

```

290
291
292 interface Deck {
293   void draw() {...}
294   void shuffle() {...}
295   void shuffleAndDraw() { this.shuffle(); this.draw(); }
296 }
297 interface Drawable {...}
298 interface SafeDeck extends Deck {...}
299 interface DrawableSafeDeck extends Drawable, SafeDeck {}
300 // main program
301 new DrawableSafeDeck().shuffleAndDraw() // SafeDeck.draw is called
302

```

The computation performed in **FHJ** is as follows:

```

303   new DrawableSafeDeck().shuffleAndDraw()
304
305   -> ((DrawableSafeDeck) new DrawableSafeDeck()).shuffleAndDraw()
306
307   -> ((Deck) new DrawableSafeDeck()).shuffle(); ((Deck) new DrawableSafeDeck()).draw()
308
309   -> ...
310
311   -> ((Deck) new DrawableSafeDeck()).draw()
312
313   -> ... // SafeDeck.draw

```

Notably, we track the static types by adding upcasts during reduction. In contrast to FJ, where **new** *C*() is a value, in **FHJ** such an expression is not a value. Instead, an expression of the form **new** *C*() is reduced to (*C*)**new** *C*(), which is a value in **FHJ** and the cast denotes the static type of the expression. This rule is applied in the first reduction step. In the second reduction step, when `shuffleAndDraw` is dispatched, the receiver (`DrawableSafeDeck`) **new** `DrawableSafeDeck()` replaces the special variable `this` by (`Deck`)**new** `DrawableSafeDeck()`. Here, the static type used in the cast (`Deck`) denotes the origin of the `shuffleAndDraw` method, which is discovered during method lookup. Later, in the fourth step, (`Deck`)**new** `DrawableSafeDeck()`.`draw()` is an instance of *hierarchical invocation*, which can be read as “finding the most specific `draw` above `DrawableSafeDeck` and along path `Deck`”. The meaning of “above `DrawableSafeDeck`” implies its supertypes, and “along path `Deck`” specifies the branch. Finally, in the last reduction step, we find the most specific version of `draw` in `SafeDeck`. In this sequence of reduction steps, the cast that tracks the origin of `shuffleAndDraw` is crucial to unambiguously find the correct implementation of `draw`. The formal procedure will be introduced in Section 3 and Section 4.

2.3 Problem 3: Overriding on Individual Branches

Method overriding is common in Object-Oriented Programming. With diamond inheritance, where conflicting methods are intended to have the same semantics, method overriding is not a problem. If conflicting methods arise from multiple parents, we can override all those methods in a single unified (or merged) method in the subclass. Therefore further overriding is simple, because there is only one method that can be overridden.

With unintentional method conflicts, however, the situation is more complicated because different, separate, conflicting methods can coexist in one class. Ideally, we would like to support overriding for those methods too, in exactly the same way that overriding is available for other (non-conflicting) methods. However, we need to be able to override the individual conflicting methods, rather than overriding all conflicting methods into a single merged one.

We illustrate the problem and the need for a more refined overriding mechanism with an example. Suppose that the programmer defines a new interface `DrawableSafeDeck` (based on the code in Section 2.2 without the old `DrawableSafeDeck`), but he needs to override `Drawable.draw` and give a new implementation of drawing so that the deck can indeed be visualized on the canvas.

2.3.1 Potential solutions/workarounds in existing languages

YANLIN: Bruno: one reviewer says S2.3.1 is "less clear", could you check again?**BRUNO:** seems ok to me. Unfortunately in all languages we know of (including C++), the existing approaches are unsatisfactory. One direction is to simply avoid this issue, by putting overriding before inheritance. For example, as shown in Figure 2(middle), we define a new component `DrawableRect` that extends `Drawable`, which simply draws the deck as a rectangle, and modifies the hierarchy:

```

350 interface DrawableRect extends Drawable {
351

```

```

352 void draw() {
353     JFrame frame = new JFrame("Canvas");
354     frame.setSize(600, 600);
355     frame.getContentPane().setBackground(Color.red);
356     frame.getContentPane().add(new Square(10,10,100,100)); ...
357 }
358 }
359 interface DrawableSafeDeck extends DrawableRect, SafeDeck {}
360

```

361 This workaround seems to work, but there are severe issues:

- 362 ■ It changes the hierarchy and existing code, hence breaks the modularity.
- 363 ■ Separate overriding is required to come after the fork inheritance, especially when the implementation needs functionality from both parents. In the above code, we have assumed that the overriding is unrelated to `Deck`. But when the drawing relies on some information of the `Deck` object, we have to either introduce field methods for delegation or change the signature of `draw` to take a parameter. Either way introduces unnecessary complexity and affects extensibility.

369 There are more involved workarounds in C++ using templates and complex patterns, but such patterns are complex to use and there are still issues. A more detailed discussion of such an approach is presented in Section 6.2.

372 2.3.2 FHJ's solution

373 An additional feature of our model is *hierarchical overriding*. It allows conflicting methods to be overridden on individual branches, hence offers independent extensibility. The above example can be easily realized by:

```

376 interface DrawableSafeDeck extends Drawable, SafeDeck {
377     void draw() override Drawable {
378         JFrame frame = new JFrame("Canvas");
379         frame.setSize(600, 600);
380         frame.getContentPane().setBackground(Color.red);
381         frame.getContentPane().add(new Square(10,10,100,100)); ...
382     }
383 }
384 // main program
385 ((Drawable)new DrawableSafeDeck()).draw(); //calls the draw in DrawableSafeDeck
386

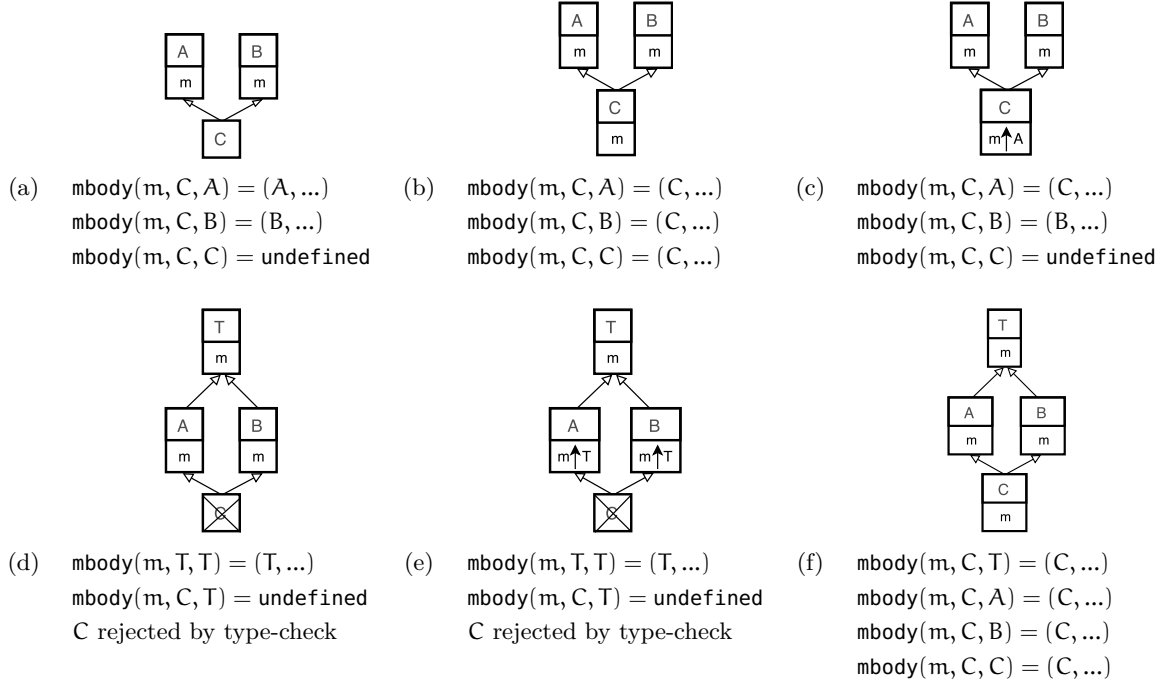

```

388 The UML graph is shown in Figure 2(right), where the up-arrow \uparrow is short for “**override**”. Here the idea is that *only* `Drawable.draw` is overridden. This is accomplished by specifying, in the method definition, that the method only overrides the `draw` from `Drawable`. The individual overriding allows us to make use of the methods from `SafeDeck` as well. In the formalization, the hierarchical overriding feature is an important feature, involved in the algorithm of hierarchical dispatch.

394 Note that, although the example here only shows one conflicting method being overridden, hierarchical overriding allows (as expected) multiple conflicting methods to be overridden in the same class.

397 2.3.3 Terminology

398 In `Drawable`, `Deck`, and `SafeDeck`, the `draw` methods are called *original methods* in this paper, because they are originally defined by the interfaces. In contrast, `DrawableSafeDeck` defines a *hierarchical overriding method*. The difference is that traditional method overriding overrides

■ **Figure 3** Examples in **FHJ**. “ $m \uparrow A$ ” stands for hierarchical overriding “ m override A ”.

all branches by defining another original method, whereas hierarchical overriding only refines one branch.

A special rule for hierarchical overriding is: it can only refine *original* methods, and cannot jump over original methods with the same signature. For instance, writing “`void draw() override Deck {...}`” is disallowed in `DrawableSafeDeck`, because the existing two branches are `Drawable.draw` and `SafeDeck.draw`, while `Deck.draw` is already covered. It does not really make sense to refine the old branch `Deck`.

2.3.4 A peek at the hierarchical dispatching algorithm

In **FHJ**, fork inheritance allows several original methods (branches) to coexist, and hierarchical dispatch first finds the most specific original method (branch), then it finds the most specific hierarchical overriding on that branch.

Before the formalized algorithm, Figure 3 gives a peek at the behavior using a few examples. The UML diagrams present the hierarchy. In (d) and (e), a cross mark indicates that the interface fails to type-check. Generally, **FHJ** rejects the definition of an interface during compilation if it reaches a diamond with ambiguity. **mbody** is the method lookup function for hierarchical dispatch, formally defined in Section 4.1. In general, $\text{mbody}(m, X, Y) = (Z, \dots)$ reflects that the source code $((Y)\text{new } X()).m()$ calls $Z.m$ at runtime. It is undefined when method dispatch is ambiguous.

In Figure 3, (a) is the base case for unintentional conflicts, namely the fork inheritance. (b) uses overriding to explicitly merge the conflicting methods. (c) represents hierarchical overriding. Our model supports diamond inheritance and can deal with diamond problems. For example, (d) and (e) are two base cases of diamond inheritance in **FHJ** and the definition of each `C` is rejected because `T` is an ambiguous parent to `C`. One solution for diamond inheritance is to merge methods coming from different parents. (f) gives a common solution

to the diamond as in Java or traits, which is to explicitly override $A.m$ and $B.m$ in C . And our calculus supports this kind of merging methods. In the last three examples, conflicting methods $A.m$ and $B.m$ should be viewed as intentional conflicts, as they come from the same source T .

BRUNO: I remember that a big complain in the reviews was talking about diamond inheritance. The Figure does have diamond inheritance but this wasn't clear to the reviewers. Please expand the text to emphasize diamond inheritance better! YANLIN: expanded.

3 Formalization

In this section, we present a formal model called **FHJ** (*Featherweight Hierarchical Java*), following a similar style as Featherweight Java [14]. **FHJ** is a minimal core calculus that formalizes the core concept of hierarchical dispatching and overriding. The syntax, typing rules and small-step semantics are presented.

3.1 Syntax

The abstract syntax of **FHJ** interface declarations, method declarations, and expressions is given in Figure 4. The multiple inheritance feature of **FHJ** is inspired by Java 8 interfaces, which supports method implementations via default methods. This feature is closely related to *traits*. To demonstrate how unintentional method conflicts are untangled in **FHJ**, we only focus on a small subset of the interface model. For example, all methods declared in an interface are either default methods or abstract methods. Default methods provide default implementations for methods. Abstract methods do not have a method body. Abstract methods can be overridden with future implementations.

3.1.1 Notations

The metavariables I, J, K range over interface names; x ranges over variables; m ranges over method names; e ranges over expressions; and M ranges over method declarations. Following Featherweight Java, we assume that the set of variables includes the special variable **this**, which cannot be used as the name of an argument to a method. We use the same conventions as FJ; we write \bar{I} as shorthand for a possibly empty sequence I_1, \dots, I_n , which may be indexed by I_i ; and write \bar{M} as shorthand for $M_1 \dots M_n$ (with no commas). We also abbreviate operations on pairs of sequences in an obvious way, writing $\bar{I} \bar{x}$ for $I_1 x_1, \dots, I_n x_n$, where n is the length of \bar{I} and \bar{x} .

3.1.2 Interfaces

YANLIN: Bruno: *acyclic, clarified herer*. In order to achieve multiple inheritance, an interface can have a set of parent interfaces, where such a set can be empty. Moreover, as usual in class-based languages, YANLIN: *refined 'acyclic'* the extension relation over interfaces is acyclic. The interface declaration **interface** I **extends** $\bar{I} \{ \bar{M} \}$ introduces an interface named I with parent interfaces \bar{I} and a suite of methods \bar{M} . The methods of I may either override methods that are already defined in \bar{I} or add new functionality special to I , we will illustrate this in more detail later.

Interfaces	IL	$::=$	<code>interface I extends \bar{I} {\bar{M}}</code>
Methods	M	$::=$	<code>I m(\bar{I}_x \bar{x}) override J {return e;} I m(\bar{I}_x \bar{x}) override J ;</code>
Expressions	e	$::=$	<code>x e.m(\bar{e}) new I() (I)e</code>
Context	Γ	$::=$	<code>$\bar{x} : \bar{I}$</code>
Values	v	$::=$	<code>(I)new J()</code>

■ **Figure 4** Syntax of **FHJ**.

3.1.3 Methods

Original methods and hierarchically overriding methods share the same syntax in our model for simplicity. The concrete method declaration `I m(\bar{I}_x \bar{x}) override J {return e;}` introduces a method named `m` with result type `I`, parameters \bar{x} of type \bar{I}_x and the overriding target `J`. The body of the method simply includes the returned expression `e`. Notably, we have introduced the **override** keyword for two cases: if the overridden interface is exactly the enclosing interface itself, then such a method is seen as originally defined **YANLIN: added an explanation** (including the case of merging methods from different branches, which can be viewed as *reborn*); otherwise it is a hierarchical overriding method. Note that in an interface `J`, `I m(\bar{I}_x \bar{x}) {return e;}` is syntactic sugar for `I m(\bar{I}_x \bar{x}) override J {return e;}`, which is the standard way of method definition in Java-like languages. The definition of abstract methods is written as `I m(\bar{I}_x \bar{x}) override J ;`, which is similar to a concrete method but without the method body. For simplicity, overloading is not modelled for methods, which implies that we can uniquely identify a method by its name.

3.1.4 Expressions & Values

Expressions can be standard constructs such as variables, method invocation, object creation, together with cast expressions. Object creation is represented by `new I()`³. Fields and primitive types are not modelled in **FHJ**. The casts are merely safe upcasts, and in fact, they can be viewed as annotated expressions, where the annotation indicates its static type. The coexistence of static and dynamic types is the key to hierarchical dispatch. A value `(I)new J()` is the final result of multiple reduction steps evaluating an expression.

For simplicity, **FHJ** does not formalize statements like assignments and so on because they are orthogonal features to the hierarchical dispatching and overriding feature. A program in **FHJ** consists of a list of interface declarations, plus a single expression.

3.2 Subtyping and Typing Rules

3.2.1 Subtyping

The subtyping of **FHJ** consists of only a few rules shown at the top of Figure 5. In short, subtyping relations are built from the inheritance in interface declarations. Subtyping is both reflexive and transitive.

³ In Java the corresponding syntax is `new I(){}`.

$$\begin{array}{c}
\boxed{I <: J} \qquad \overline{I <: I} \\
\\
\frac{I <: J \quad J <: K}{I <: K} \qquad \frac{\text{interface } I \text{ extends } I_1, I_2, \dots, I_n \{\overline{M}\}}{I <: I_1, I <: I_2, \dots, I <: I_n} \\
\\
\boxed{\Gamma \vdash e : I} \qquad (T\text{-VAR}) \Gamma \vdash x : \Gamma(x) \\
\\
(T\text{-INVK}) \frac{\Gamma \vdash e_0 : I_0 \quad \text{mbody}(m, I_0, I_0) = (K, \bar{J} \bar{x}, I _) \quad \Gamma \vdash \bar{e} : \bar{I} \quad \bar{I} <: \bar{J}}{\Gamma \vdash e_0.m(\bar{e}) : I} \\
\\
(T\text{-NEW}) \frac{\text{interface } I \text{ extends } \bar{I} \{\overline{M}\} \quad \text{canInstantiate}(I)}{\Gamma \vdash \text{new } I() : I} \\
\\
(T\text{-ANNO}) \frac{\Gamma \vdash e : I \quad I <: J}{\Gamma \vdash (J)e : J} \\
\\
(T\text{-METHOD}) \frac{I <: J \quad \text{findOrigin}(m, I, J) = \{J\} \quad \text{mbody}(m, J, J) = (K, \bar{I}_x \bar{x}, I_e _) \quad \bar{x} : \bar{I}_x, \text{this} : I \vdash e_0 : I_0 \quad I_0 <: I_e}{I_e \ m(\bar{I}_x \bar{x}) \text{ override } J \{ \text{return } e_0; \} \text{ OK IN } I} \\
\\
(T\text{-ABSMETHOD}) \frac{I <: J \quad \text{findOrigin}(m, I, J) = \{J\} \quad \text{mbody}(m, J, J) = (K, \bar{I}_x \bar{x}, I_e _)}{I_e \ m(\bar{I}_x \bar{x}) \text{ override } J; \text{ OK IN } I} \\
\\
(T\text{-INTF}) \frac{\overline{M} \text{ OK IN } I \quad \forall J :> I \text{ and } m, \text{mbody}(m, J, J) \text{ is defined} \Rightarrow \text{mbody}(m, I, J) \text{ is defined} \quad \forall J :> I \text{ and } m, [m \text{ override } I] \text{ and } J[m \text{ override } J] \text{ defined} \Rightarrow \text{canOverride}(m, I, J)}{\text{interface } I \text{ extends } \bar{I} \{\overline{M}\} \text{ OK}}
\end{array}$$

■ **Figure 5** Subtyping and Typing Rules of **FHJ**.

3.2.2 Type-checking

Details of type-checking rules are displayed at the bottom of Figure 5, including expression typing, well-formedness of methods and interfaces. As a convention, an environment Γ is maintained to store the types of variables, together with the self-reference **this**.

(T-INVK) is the typing rule for method invocation. Naturally, the receiver and the arguments are required to be well-typed. **mbody** is our key function for method lookup that implements the hierarchical dispatching algorithm. The formal definition will be introduced in Section 4. Here **mbody**(m, I_0, I_0) finds the most specific m above I_0 . “Above I_0 ” specifies the search space, namely the supertypes of I_0 including itself. For the general case, however, the hierarchical invocation **mbody**(m, I, J) finds “the most specific m above I and along path/branch J ”. “Along path J ” additionally requires the result to relate to J , that is to say, the most specific interface that has a subtyping relationship with J .

In (T-INVK), as the compilation should not be aware of the dynamic type, it only requires that invoking m is valid for the static type of the receiver. The result of **mbody** contains

the interface that provides the most specific implementation, the parameters and the return type. We use underscore for the return expression, matching both implemented and abstract methods. **YANLIN: refined.**

(T-NEW) is the typing rule for object creation `new I()`. The auxiliary function `canInstantiate(I)` (see definition in Section 4.4) checks whether an interface `I` can be instantiated or not. Since fork inheritance accepts conflicting branches to coexist, the check requires that the most specific method is concrete for each method on each branch.

(T-METHOD) is more interesting since a method can either be an original method or a hierarchical overriding, though they share the same syntax and method typing rule. `findOrigin(m, I, J)` is a fundamental function, used to find “the most specific interfaces that are above `I` and along path `J`, and originally defines `m`” (see Section 4 for full definition). By “most specific interfaces”, it implies that the inherited supertypes are excluded. Thus the condition `findOrigin(m, I, J) = {J}` indicates a characteristic of a hierarchical overriding: it must override an original method; the overriding is direct and there does not exist any other original method `m` in between. Then `mbody(m, J, J)` provides the type of the original method, so hierarchical overriding has to preserve the type. Finally the return expression is type-checked to be subtype of the declared return type. For the definition of an original method, `I` equals `J` and the rule is straightforward. (T-ABSMETHOD) is a similar rule but works on abstract method declarations.

(T-INTF) defines the typing rule on interfaces. The first condition is obvious, namely its methods need to be well checked. The third condition checks whether the overriding between original methods preserves typing. In this condition we again use some helper functions defined in Section 4. `I[m override I]` is defined if `I` originally defines `m`, and `canOverride(m, I, J)` checks whether `I.m` has the same type as `J.m`. Generally the preservation of method type is required for any supertype `J` and any method `m`.

The second condition of (T-INTF) is more complex and is the key to type soundness. Unlike C++ which rejects on ambiguous calls, **FHJ** rejects on the definition of interfaces when they form a diamond. Consider the case when the second condition is broken: `mbody(m, J, J)` is defined but `mbody(m, I, J)` is undefined for some `J` and `m`. This indicates that `m` is available and unambiguous from the perspective of `J`, but is ambiguous to `I` on branch `J`. It means that there are multiple overriding paths of `m` from `J` to `I`, which form a diamond. Hence rejecting that case meets our expectation. Below is an example (Figure 3 (e)) that illustrates the reason why this condition is needed:

```

539 interface T          { T m() override T { return new T(); } }
540 interface A extends T { T m() override T { return new A(); } }
541 interface B extends T { T m() override T { return new B(); } }
542 interface C extends A, B {}
543 ((T) new C()).m()
544

```

This program does not compile on interface `C`, because of the second condition in (T-INTF), where `I` equals `C` and `J` equals `T`. By the algorithm, `mbody(m, T, T)` will refer to `T.m`, but `mbody(m, C, T)` is undefined, since both `A.m` and `B.m` are most specific to `C` along path `T`, which forms a diamond. The expression `((T)new C()).m()` is one example of triggering ambiguity, but **FHJ** simply rejects the definition of `C`. To resolve the issue, the programmer needs to have an overriding method in `C`, to explicitly merge the conflicting ones.

Finally, rule (T-ANNO) is the typing rule for a cast expression. By the rule, only upcasts are valid.

3.3 Small-step Semantics and Propagation

Figure 6 defines the small-step semantics and propagation rules of **FHJ**. When evaluating an expression, they are invoked and produce a single value in the end.

3.3.1 Semantic Rules

(S-INVK) is the only computation rule we need for method invocation. As a small-step rule and by congruence, it assumes that the receiver and the arguments are already values. Specifically, the receiver $(J)\text{new } I()$ indicates the dynamic type I together with the static type J . Therefore $\text{mbody}(m, I, J)$ carries out hierarchical dispatching, acquires the types, the return expression e_0 and the interface I_0 which provides the most specific method. Here we use e_0 to imply that the return expression is forced to be non-empty because it requires a concrete implementation. Now the rule reduces method invocation to e_0 with substitution. Parameters are substituted with arguments, and the **this** reference is substituted with the receiver, and in the meanwhile the static types are recorded via annotations. Finally, the return type I_e is put in the front as an annotation.

3.3.2 Propagation Rules

(C-RECEIVER), (C-ARGS) and (C-FREDUCE) are natural propagation rules on receivers, arguments, and cast-expressions, respectively. (C-STATIC TYPE) automatically adds an annotation I to the new object $\text{new } I()$. (C-ANNOREDUCE) merges nested upcasts into a single upcast with the outermost type.

4 Key Algorithms and Type-Soundness

In this section, we present the fundamental algorithms and auxiliary definitions used in our formalization and show that the resulting calculus is type sound. The functions presented in this section are the key components that implement our algorithm for method lookup.

4.1 The Method Lookup Algorithm in mbody

$\text{mbody}(m, I_d, I_s)$ denotes the method body lookup function. We use I_d, I_s , since mbody is usually invoked by a receiver of a method m , with its dynamic type I_d and static type I_s . Such a function returns the most specific method implementation. **YANLIN: Refined.** More accurately, mbody returns $(J, \overline{I_x} \ \overline{x}, I_e \ e_0)$ where J is the found interface that contains the desired method; $\overline{I_x} \ \overline{x}$ are the parameters and its types, e_0 is the returned expression (empty for abstract methods). It considers both originally-defined methods and hierarchical overriding methods, so findOrigin and findOverride (see the definition in Section 4.2 and Section 4.3) are both invoked. The formal definition gives the expected results for the earlier examples in Figure 3.

$$\begin{array}{c}
\text{(S-INVK)} \frac{\text{mbody}(\mathbf{m}, \mathbf{I}, \mathbf{J}) = (\mathbf{I}_0, \overline{\mathbf{I}_x} \ \overline{\mathbf{x}}, \mathbf{I}_e \ e_0)}{((\mathbf{J})\text{new } \mathbf{I}()) . \mathbf{m}(\overline{\mathbf{v}}) \rightarrow (\mathbf{I}_e)[(\overline{\mathbf{I}_x})\overline{\mathbf{v}}/\overline{\mathbf{x}}, (\mathbf{I}_0)\text{new } \mathbf{I}()/\text{this}]e_0} \\
\\
\text{(C-RECEIVER)} \frac{e_0 \rightarrow e'_0}{e_0 . \mathbf{m}(\overline{\mathbf{e}}) \rightarrow e'_0 . \mathbf{m}(\overline{\mathbf{e}})} \quad \text{(C-ARGS)} \frac{e \rightarrow e'}{e_0 . \mathbf{m}(\dots, e, \dots) \rightarrow e_0 . \mathbf{m}(\dots, e', \dots)} \\
\\
\text{(C-STATIC TYPE)} \frac{}{\text{new } \mathbf{I}() \rightarrow (\mathbf{I})\text{new } \mathbf{I}()} \\
\\
\text{(C-FREDUCE)} \frac{e \rightarrow e' \quad e \neq \text{new } \mathbf{J}()}{(\mathbf{I})e \rightarrow (\mathbf{I})e'} \\
\\
\text{(C-ANNOREDUCE)} (\mathbf{I})((\mathbf{J})\text{new } \mathbf{K}()) \rightarrow (\mathbf{I})\text{new } \mathbf{K}()
\end{array}$$

■ **Figure 6** Small-step semantics.

587 \triangleright *Definition of* $\text{mbody}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s)$:

588 • $\text{mbody}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s) = (\mathbf{J}, \overline{\mathbf{I}_x} \ \overline{\mathbf{x}}, \mathbf{I}_e \ e_0)$

589 with: $\text{findOrigin}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s) = \{\mathbf{I}\}$

590 $\text{findOverride}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}) = \{\mathbf{J}\}$

591 $\mathbf{J}[\mathbf{m} \text{ override } \mathbf{I}] = \mathbf{I}_e \ \mathbf{m}(\overline{\mathbf{I}_x} \ \overline{\mathbf{x}}) \text{ override } \mathbf{I} \{\text{return } e_0;\}$

592 • $\text{mbody}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s) = (\mathbf{J}, \overline{\mathbf{I}_x} \ \overline{\mathbf{x}}, \mathbf{I}_e \ \emptyset)$

593 with: $\text{findOrigin}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s) = \{\mathbf{I}\}$

594 $\text{findOverride}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}) = \{\mathbf{J}\}$

595 $\mathbf{J}[\mathbf{m} \text{ override } \mathbf{I}] = \mathbf{I}_e \ \mathbf{m}(\overline{\mathbf{I}_x} \ \overline{\mathbf{x}}) \text{ override } \mathbf{I};$

596

597

598

599 To calculate $\text{mbody}(\mathbf{m}, \mathbf{I}_d, \mathbf{I}_s)$, the invocation of `findOrigin` looks for the most specific
600 original methods and their interfaces, and expects a singleton set, so as to achieve unambiguity.
601 Furthermore, the invocation of `findOverride` also expects a unique and most specific
602 hierarchical override. And finally the target method is returned.

603 4.2 Finding the Most Specific Origin: `findOrigin`

604 We proceed to give the definitions of two core functions that support method lookup, namely
605 `findOrigin` and `findOverride`. Generally, `findOrigin`($\mathbf{m}, \mathbf{I}, \mathbf{J}$) finds the set of most specific
606 interfaces where \mathbf{m} is originally defined. Interfaces in this set should be above interface \mathbf{I}
607 and along path \mathbf{J} . Finally with `prune` (defined in Section 4.4) the overridden interfaces will
608 be filtered out.

609 \triangleright *Definition of findOrigin(m, I, J) :*

610 • $\text{findOrigin}(m, I, J) = \text{prune}(\text{origins})$

611 with: $\text{origins} = \{K \mid I <: K, \text{ and } K <: J \vee J <: K,$
 612 $\text{ and } K[m \text{ override } K] \text{ is defined}\}$
 613

614 By the definition, an interface belongs to $\text{findOrigin}(m, I, J)$ if and only if:

- 615 ■ It originally defines m ;
- 616 ■ It is a supertype of I (including I);
- 617 ■ It is either a supertype or a subtype of J (including J);
- 618 ■ Any subtype of it does not belong to the same result set because of prune .

619 4.3 Finding the Most Specific Overriding: findOverride

620 The findOrigin function only focuses on original method implementations, where all
 621 the hierarchical overriding methods are omitted during that step. On the other hand,
 622 $\text{findOverride}(m, I, J)$ has the assumption that J defines an original m , and this function
 623 tries to find the interfaces with the most specific implementations that hierarchically overrides
 624 such an m . Formally,

625 \triangleright *Definition of findOverride(m, I, J) :*

626 • $\text{findOverride}(m, I, J) = \text{prune}(\text{overrides})$

627 with: $\text{overrides} = \{K \mid I <: K, K <: J \text{ and } K[m \text{ override } J] \text{ is defined}\}$
 628

629 By the definition, an interface belongs to $\text{findOverride}(m, I, J)$ if and only if:

- 631 ■ it is between I and J (including I, J);
- 632 ■ it hierarchically overrides $J.m$;
- 633 ■ any subtype of it does not belong to the same set.

634 4.4 Other Auxiliaries

635 Below we give other minor definitions of the auxiliary functions that are used in previous
 636 sections.

637 \triangleright *Definition of $I[m \text{ override } J]$:*

638 • $I[m \text{ override } J] = I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } J \ \{\text{return } e_0;\}$

639 with: interface I extends $\overline{I} \ \{I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } J \ \{\text{return } e_0;\} \dots\}$

640 • $I[m \text{ override } J] = I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } J$;

641 with: interface I extends $\overline{I} \ \{I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } J ; \dots\}$

642
643

644 Here $I[m \text{ override } J]$ is basically a direct lookup for method m in the body of I , where such
 645 a method overrides J (like static dispatch). The method can be either concrete or abstract,

646 and the body of definition is returned. Notice that by our syntax, $I[m \text{ override } I]$ is looking
 647 for the originally-defined method m in I .

648 \triangleright *Definition of $\text{prune}(\text{set})$:*

649 • $\text{prune}(\text{set}) = \{I \in \text{set} \mid \nexists J \in \text{set} \setminus I, J <: I\}$
 650

651 The prune function takes a set of types, and filters out those that have subtypes in the
 652 same set. In the returned set, none of them has subtyping relation to one another, since all
 653 supertypes have been removed.

654 \triangleright *Definition of $\text{canOverride}(m, I, J)$:*

655 • $\text{canOverride}(m, I, J)$ holds

656 iff: $I[m \text{ override } I] = I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } I \dots$

657 $J[m \text{ override } J] = I_e \ m(\overline{I_x} \ \overline{y}) \text{ override } J \dots$
 658

659 canOverride just checks that two original m in I and J have the same type.

660 \triangleright *Definition of $\text{canInstantiate}(I)$:*

661 • $\text{canInstantiate}(I)$ holds

662 iff: $\forall m, \forall J \in \text{findOrigin}(m, I, I), \text{findOverride}(m, I, J) = \{K\},$

663 and $K[m \text{ override } J] = I_e \ m(\overline{I_x} \ \overline{x}) \text{ override } J \{\text{return } e_0; \}$
 664

665 $\text{canInstantiate}(I)$ checks whether interface I can be instantiated by the keyword **new**.
 666 $\text{findOrigin}(m, I, I)$ represents the set of branches I inherits on method m . I can be in-
 667 stantiated if and only if for every branch, the most specific implementation is non-abstract.
 668 **YANLIN:** removed 'unambiguous'.

669 4.5 Properties

670 We present the type soundness of the model by a few theorems below, following the standard
 671 technique of subject reduction and progress proposed by Wright and Felleisen [35]. The
 672 proof, together with some lemmas, is presented in Appendix. Type soundness states that if
 673 an expression is well-typed, then after many reduction steps it must reduce to a value, and
 674 its annotation is the same as the static type of the original expression.

675 \blacktriangleright **Theorem 1** (Subject Reduction). *If $\Gamma \vdash e : I$ and $e \rightarrow e'$, then $\Gamma \vdash e' : I$.*

676 **Proof.** See Appendix A.1. ◀

677 \blacktriangleright **Theorem 2** (Progress). *Suppose e is a well-typed expression, if e includes $((J)\text{new } I()) \cdot m(\overline{v})$
 678 as a sub-expression, then $mbody(m, I, J) = (I_0, \overline{I_x} \ \overline{x}, I_e \ e_0)$ and $\#(\overline{x}) = \#(\overline{v})$ for some $I_0, \overline{I_x},$
 679 \overline{x}, I_e and e_0 .*

680 **Proof.** See Appendix A.1. ◀

681 \blacktriangleright **Theorem 3** (Type Soundness). *If $\phi \vdash e : I$ and $e \rightarrow^* e'$ with e' a normal form, then e' is
 682 a value v with $\phi \vdash v : I$.*

683 **Proof.** Immediate from Theorem 1 and Theorem 2. ◀

684 Note that in Theorem 2, “ $\#(\bar{x})$ ” denotes the length of \bar{x} .

685 Our theorems are stricter than those of Featherweight Java [14]. In FJ, the subject
686 reduction theorem states that after a step of reduction, the type of an expression may change
687 to a subtype due to subtyping. However, in **FHJ**, the type remains unchanged because we
688 keep track of the static types and use them for casting during reduction.

689 Finally we show that one-step evaluation is deterministic. This theorem is helpful to
690 show that our model of multiple inheritance is not ambiguous (or non-deterministic).

691 ► **Theorem 4** (Determinacy of One-Step Evaluation). *If $t \rightarrow t'$ and $t \rightarrow t''$, then $t' = t''$.*

692 **Proof.** See Appendix A.1. ◀

693 5 Discussion

694 In this section, we will discuss the design space and reflect about some of the design decisions
695 of our work. We relate our language to traits, Java interfaces as well as other languages.
696 Furthermore, we discuss ways to improve our work.

697 **YANLIN: marco:** The whole section 5 may benefit some English proofreading, but I'm too
698 bad at English to really help... may be Bruno can give some more support here?

699 5.1 Abstract Methods

700 Abstract methods are one of the key features in most general OO languages. For example,
701 Java interfaces were designed to include only method declarations, and those abstract methods
702 can be implemented in a class body. The formal Featherweight Java model [14] does not
703 include abstract methods because of the orthogonality to the core calculus. In traits, a
704 similar idea is to use keywords like “**require**” for abstract method declarations [28]. Abstract
705 methods provide a way to delay the implementations to future subtypes. Using overriding,
706 they also help to “exclude” existing implementations.

707 In our formalized calculus, however, abstract methods are not a completely orthogonal
708 feature. The `canInstantiate` function has to check whether an interface can be instantiated
709 by looking at all the inherited branches and checking if each most specific method is concrete
710 or not.

711 Our formalization has a simple form of abstract methods, which behave similarly to
712 conventional methods with respect to conflicts. Other languages may behave differently.
713 For instance, in Java 8 when putting two identical abstract methods together by multiple
714 inheritance, there is no conflict error. In Figure 7, we use italic *m* to denote abstract methods.
715 In both cases, the Java compiler accepts the definition of C and automatically merges the
716 two inherited methods *m* into a single one. **FHJ** behaves differently from Java in both cases.
717 In the fork inheritance case (left), C will have two distinct abstract methods corresponding
718 to *A.m* and *B.m*. In the diamond inheritance case, the definition of C is rejected. There are
719 two reasons for this difference in behaviour. Firstly, our formalization just treats abstract
720 methods as concrete methods with an empty body, and that simplifies the rules and proofs
721 a lot. Secondly, and more importantly, we distinguish and treat differently conflicting
722 methods, since they may represent different operations, even if they are abstract. Thus our
723 model adopts a very conservative behavior rather than automatically merging methods by
724 default (as done in many languages). **YANLIN: 717: we could mention that Godez (the guy**
725 **maintaining java now) would prefer if Java behaved like our formalization but he can not for**
726 **retrocompatibility. Re: where do you think is the proper place to mention this?** Arguably,
727 for the diamond case, as we have mentioned, it is actually an intentional conflict due to the

■ **Figure 7** Fork inheritance (left) and diamond inheritance (right) on abstract methods.

same source T . It is possible to change our model to account for other behaviors for abstract methods, but we view this as a mostly orthogonal change to our work, which should not affect the essence of the model presented here.

5.2 Orthogonal & Non-Orthogonal Extensions

Our model is designed as a minimal calculus that focuses on resolving unintentional conflicts. Therefore, we have omitted a number of common orthogonal features including primitive types, assignments, method overloading, covariant method return types, static dispatch, and so on. Those features can, in principle, be modularly added to the model without breaking type soundness. For example, we present the additional syntax, typing and semantic rules of static invocation below as an extension:

$$\begin{aligned}
 \text{Expressions } e &::= \dots \mid e.J_0@J_1 :: m(\bar{e}) \\
 \text{(T-STATICINVK)} \quad &\frac{J_0[m \text{ override } J_1] = I \ m(\bar{J} \ \bar{x}) \text{ override } J_1 \ \{\text{return } e;\} \quad \Gamma \vdash e_0 : I_0 \quad I_0 <: J_0 \quad \Gamma \vdash \bar{e} : \bar{I} \quad \bar{I} <: \bar{J}}{\Gamma \vdash e_0.J_0@J_1 :: m(\bar{e}) : I} \\
 \text{(S-STATICINVK)} \quad &\frac{J_0[m \text{ override } J_1] = I_e \ m(\bar{I}_x \ \bar{x}) \text{ override } J_1 \ \{\text{return } e_0;\} \quad ((J) \text{new } I()) . J_0@J_1 :: m(\bar{v}) \rightarrow (I_e)[(\bar{I}_x)\bar{v}/\bar{x}, (J_0) \text{new } I()/\text{this}]e_0}{((J) \text{new } I()) . J_0@J_1 :: m(\bar{v}) \rightarrow (I_e)[(\bar{I}_x)\bar{v}/\bar{x}, (J_0) \text{new } I()/\text{this}]e_0}
 \end{aligned}$$

A static invocation $e.J_0@J_1 :: m(\bar{e})$ aims at finding the method m in J_0 that hierarchically overrides J_1 , thus $J_0[m \text{ override } J_1]$ is invoked. As shown in (S-STATICINVK), static dispatch needs a receiver for the substitution of the “`this`” reference, so as to provide the latest implementations. In fact, static dispatch is common in OO programming, as it provides a shortcut to the reuse of old implementation easily, and super calls can also rely on this feature. For convenience we just make it simple above, whereas in languages like C++ or Java, the static or super invocations are more flexible, as they can climb the class hierarchy.

YANLIN: Bruno: discussed multiple overriding and the two designs One non-orthogonal extension to **FHJ** could be to generalize the model to allow multiple hierarchical method overriding, meaning that, we allow overriding methods to update multiple branches instead of only one branch. It offers a more fine-grained mechanism for merging, and can be helpful to easily understand the structure of the hierarchy. Multiple overriding would be useful in the following situation, for example:

```

interface A { void m() { ... } }
interface B { void m() { ... } }
interface C { void m() { ... } }
interface D extends A, B, C {

```

```

756 void m() override A,B {...} // overrides branches A and B only
757 void m() override C {...} // overrides branch C
758 }

```

Here **D** inherits from three interfaces **A**, **B**, **C** with conflicting methods **m**, but only merges two of those methods. While we can simulate **D** without multiple overriding in our calculus (by introducing an intermediate class), a better approach would be to support multiple overriding natively.

We present the modification of syntax, typing and semantic rules below (abstract methods omitted):

$$\begin{array}{c}
 \text{Methods } M ::= \dots \mid I \, m(\overline{I_x} \, \overline{x}) \text{ override } \overline{J} \{ \text{return } e; \} \\
 \\
 \text{(T-MOMETHOD)} \quad \frac{\forall J_i \in \overline{J}, I <: J_i \quad \text{findOrigin}(m, I, J_i) = \{J_i\} \quad \text{mbody}(m, J_i, J_i) = (K, \overline{I_x} \, \overline{x}, I_e \, _)}{I_e \, m(\overline{I_x} \, \overline{x}) \text{ override } \overline{J} \{ \text{return } e_0; \} \text{ OK IN } I} \quad \overline{x} : \overline{I_x}, \text{this} : I \vdash e_0 : I_0 \quad I_0 <: I_e
 \end{array}$$

Semantic rules themselves remain unchanged, however, we need to change slightly the definition of **findOverride** in **mbody**:

▷ *Definition of findOverride(m, I, J):*

• **findOverride(m, I, J) = prune(overrides)**

with: **overrides** = {**K** | **I** <: **K**, **K** <: **J** and **K**[**m** override **J**] where **J** ∈ **J**}

With this approach, branches **A** and **B** are merged in the sense that they share the same code, which can be separately updated in future interfaces. Another approach would be to deeply merge the branches, with similar effect as introducing an intermediate interface **AB** to explicitly merge the two branches. However, this approach is problematic because there is no clear mechanism of identifying and further updating the merged branches. This could be an interesting future work to explore.

Other typical non-orthogonal extensions to **FHJ** could be to have fields. The design of **FHJ** can be viewed as a variant of Java 8 with default methods which allows for unintentional method conflicts. Like Java interfaces and traits, state is forbidden in **FHJ**. There are some inheritance models that also account for fields, such as C++ that uses virtual inheritance [10]. In our model, however, we can perhaps borrow the idea of *interface-based programming* [33], which models state with abstract state operations. This can be realized by extending our current model with static methods and anonymous classes from Java. However such an extension requires more thought, so we leave it to future work.

5.3 Loosening the Model: Reject Early or Reject Later?

FHJ rejects the following case of diamond inheritance:

```

789 interface A { void m() {...} }
790 interface B extends A { void m() {...} }
791 interface C extends A { void m() {...} }
792 interface D extends B, C {}
793
794

```

Here both **B.m** and **C.m** override **A.m**, and **D** inherits both conflicting methods without an explicit override. In this case, automatically merging the two methods (to achieve diamond

inheritance) is not possible, which is why many models (like traits and Java 8) reject such programs. Moreover, keeping the two method implementations in \mathbf{D} is problematic. In essence, hierarchical information is not helpful to disambiguate later method calls, since the two methods share the same origin ($\mathbf{A.m}$). Our calculus rejects such conflicts by the (T-INTF) rule, where \mathbf{D} is considered to be ill-formed. We believe that rejecting \mathbf{D} follows the principle of models like traits and Java 8 interfaces, where the language/type-system is meant to alert the programmer for a possible conflict early.

Nonetheless, C++ accepts the definition of \mathbf{D} , but forbids later upcasts from \mathbf{D} to \mathbf{A} because of ambiguity. Our language is more conservative on definitions of interfaces compared to C++, but on the upside, upcasts are not rejected. We could also loosen the model to accept definitions such as \mathbf{D} , and perform ambiguity check on upcasts and other expressions. Then, we would need to handle more cases than C++ because of the complication caused by the hierarchical overriding feature.

6 Related Work

We describe related work in four parts. We first discuss mainstream popular multiple inheritance models and then some specific models (e.g., C++ and C#) which are closest to our work. Then we discuss related techniques used in **SELF**. Finally, we discuss the foundation and related work of our formalization.

6.1 Mainstream Multiple Inheritance Models

Multiple inheritance is a useful feature in object-oriented programming, although it is difficult to model and can cause various problems (e.g. the diamond problem [27, 29]). There are many existing languages/models that support multiple inheritance [10, 22, 5, 28, 17, 19, 20, 11, 2]. The mixin models [5, 11, 32, 2, 13] allow naming components that can be applied to various classes as reusable functionality units. However, the linearization (total ordering) of mixin inheritance cannot provide a satisfactory resolution in some cases and restricts the flexibility of mixin composition. Scala traits [22] are in fact linearized mixins and hence have the same problem as mixins.

Simplifying the mixins approach, traits [28, 9] draw a strong line between units of reuse and object factories. Traits act as units of reuse, containing functionality code. Classes, on the other hand, are assembled from traits and act as object factories. Java 8 interfaces are closely related to traits: concrete method implementations are allowed (via the **default** keyword) inside interfaces, thus allowing for a restricted form of multiple inheritance. There are also proposals such as FeatherTrait Java [16] for extending Java with traits. Extensions [25, 26] to the original trait model exists with various advanced features, such as *renaming*. As discussed in Section 2, the renaming feature gives a workaround to the unintentional method conflicts problem. However, it breaks structural subtyping.

Malayeri and Aldrich proposed a model CZ [17] which aims to do multiple inheritance without the diamond problem. Inheritance is divided into two concepts: inheritance dependency and implementation inheritance. Using a combination of **requires** and **extends**, a program with diamond inheritance is transformed to one without diamonds. Moreover, fields and multiple inheritance can coexist. However untangling inheritance also untangles the class structure. In CZ, not only the number of classes but also the class hierarchy complexity increases.

The above-mentioned models/languages support multiple inheritance, focusing on diamond inheritance. They handle method conflicts in the same way, by simply disallowing two

methods with the same signature from two different units to coexist. In contrast, our work provides mechanisms that allow methods with the same signatures, but different parents to coexist in a class. Disambiguation is possible in many cases by using both static and dynamic type information during method dispatching. In the cases where real ambiguity exists, **FHJ**'s type system can reject interface definitions and/or method calls statically.

6.2 Resolving Unintentional Method Conflicts

A few language implementations have realized the problem of unintentional conflicts and provide some support for it.

C++ model. C++ supports a very flexible inheritance model. C++ allows the existence of unintentional conflicts and users may specify a hierarchical path via casts for disambiguation, as discussed in Section 2. With virtual methods, dynamic dispatch is used and the method lookup algorithm will find the most specific method definition. A contribution of our work is to provide a minimal formal model of hierarchical dispatching, whereas C++ can be viewed as a real-world implementation. There are several formalizations [34, 24, 23] in the literature modeling various C++ features. However, as far as we know, there is no formal model that captures this aspect of the C++ method dispatching model. Apart from this, as discussed in Section 5.3, **FHJ** conservatively rejects some interface/class definitions that C++ accepts, and upcasts are never rejected since the ambiguity is prevented beforehand. **YANLIN: fixed.**

Although C++ supports hierarchical dispatching, it does not support hierarchical overriding. However, there are some possible workarounds that can mimick hierarchical overriding, including the *MiddleMan* approach⁴, the *interface classes* pattern as described in Section 25.6 of [31], the *LotterySimulation* discussion in [30]. Since these workarounds share the same spirit, we will discuss in detail the *MiddleMan* approach, with the code shown in Figure 8. In this example, classes **A** and **B** are two classes that both define a method with the same name **m** unintentionally.

Class **MiddleMan**, as its name suggests, acts as a middle man between its class **C** and its parents **A**, **B**. **MiddleMan** defines a virtual method **m** that overrides a parent method **m** and delegates the implementation to another method **m_impl** that takes **this** as a parameter. C++ supports method overloading, so that multiple **m_impl** methods with different parameter types can coexist. When defining class **C**, we specify the parents to be **MiddleMan<A>**, **MiddleMan** instead of **A**, **B**. In this way, programmers may define new versions of **A.m** and **B.m** in class **C** by providing the corresponding **m_impl** methods. Then in the client code, the method call **((A*)c)->m()** will print out string **"MA2"**, as expected. Although this workaround can help us defining partial method overrides to a certain extent, the drawbacks are obvious. Firstly, the approach is complex and requires the programmer to fully understand this approach. Moreover, the lack of direct syntax support makes **MiddleMan** code cumbersome to write. Finally, the approach is ad-hoc, meaning that the class **MiddleMan** shown in Figure 8 is not general enough to be used in other cases: more middle-men are needed if partial method overrides happen in other classes; and it is even worse when return types differ.

C# explicit method implementations. Explicit method implementations is a special feature supported by C#. As described in C# documentation [19], a class that implements an interface can explicitly implement a member of that interface. When a member is explicitly

⁴ <https://stackoverflow.com/questions/44632250/can-i-do-mimic-things-like-this-partial-override-in-c>

```

class A { public: virtual void m() {cout << "MA" << endl;}};
class B { public: virtual void m() {cout << "MB" << endl;}};
template<class C>
class MiddleMan : public C {
    void m() override final { m_impl(this); }
protected:
    virtual void m_impl(MiddleMan*) { return this->C::m(); }
};
class C : public MiddleMan<A>, public MiddleMan<B> {
private:
    void m_impl (MiddleMan<A>*) override {cout << "MA2" << endl;}
    void m_impl (MiddleMan<B>*) override {cout << "MB2" << endl;}
};
int main()
{
    C* c = new C();
    ((A*)c)->m();    //print "MA2"
    return 0;
}

```

■ **Figure 8** The *MiddleMan* approach.

implemented, it can only be accessed through an instance of the interface. Explicit interface implementations allow an interface to inherit multiple interfaces that share the same member names and give each interface member a separate implementation.

Explicit interface member implementations have two advantages. Firstly, they allow interface implementations to be excluded from the public interface of a class. This is particularly useful when a class implements an internal interface that is of no interest to a consumer of that class or struct. Secondly, they allow disambiguation of interface members with the same signature. However, there are two critical differences to **FHJ**: (1) default method implementations are not allowed in C# interfaces; (2) there is only one level of conflicting method implementations at the class that implements the multiple parent interfaces. Further overriding of those methods is not possible in subclasses.

Languages using hygienicity. In NextGen/MixGen [1], HygJava [15] and Magda [3], *hygienicity* is proposed to deal with unintentional method conflicts. The idea is to give a method a unique identifier by prefixing the name with an unambiguous path. As shown in Figure 9, the prefix `HelloWorld` in method call `(new HelloWorld []).HelloWorld.MainMatter()` is mandatory. So writing programs in these languages is tedious if not supported by a specialized IDE, that aids filling prefix/method information. The advantage of this approach, compared to ours, is that it does not require any additional notion for method dispatching. Indeed the compilation strategy is simple, just by generating conventional code (say in Java or C++) with method names attached with prefixes. Unfortunately, the disadvantage is that some expressive power is lost. In particular *merging* methods arising from diamond inheritance is not possible because the methods have different prefixes. As shown in Figure 10, two methods `m` from different branches `A` and `B` cannot be overridden by the method `m` in `C` because they are regarded as unrelated methods, and `m` in `C` is just another new method that has nothing to do with `A.m` or `B.m`. The reason is that in these hygienic approaches, path names are used to distinguish different methods. In contrast, our model can deal with unintentional conflicts, as well as merged methods because our semantics is not simply based on prefixing. Instead, our model keeps the names of methods unchanged, and our direct operational semantics takes static and dynamic type information into account at runtime

```

mixin HelloWorld of Object =
  new Object MainMatter()
  begin
    "Hello world".String.print();
  end;
end;
(new HelloWorld []).HelloWorld.MainMatter();

```

■ **Figure 9** Full-qualified name of method calls in Magda.

```

mixin A of Object =
  new String m()
  begin
    return "A";
  end;
end;
mixin B of Object =
  new String m()
  begin
    return "B";
  end;
end;
mixin C of A, B =
  new String m()
  begin
    return "C";
  end;
end;

```

■ **Figure 10** Code in Magda.

914 when doing method dispatching. Finally, the multiple inheritance model in Magda is based
 915 on Mixins, whereas **FHJ** is based on traits. Thus, Magda inherits all limitations of Mixins
 916 (such as the linearization problem, etc).

917 6.3 Hierarchical Dispatch in SELF

918 As we have discussed before, although the mix of static and dynamic dispatch is particularly
 919 useful under certain circumstances, it has received little research attention. In the prototype-
 920 based language **SELF** [6], inheritance is a basic feature. **SELF** does not include classes but
 921 instead allows individual objects to inherit from (or delegate to) other objects. Although it
 922 is different from class-based languages, the multiple inheritance model is somewhat similar.
 923 The **SELF** language supports multiple (object) inheritance in a clever way. It not only
 924 develops the new inheritance relation with *prioritized parents* but also adopts *sender path*
 925 *tiebreaker rule* for method lookup. In **SELF** “*if two slots with the same name are defined in*
 926 *equal-priority parents of the receiver, but only one of the parents is an ancestor or descendant*
 927 *of the object containing the method that is sending the message, then that parent’s slot takes*
 928 *precedence over the over parent’s slot*”. Similarly to our model, this sender path tiebreaker
 929 rule resolves ambiguities between unrelated slots. However, it is used in a prototype-based
 930 language setting and it does not support method hierarchical overriding as **FHJ** does.

6.4 Formalization Based on Featherweight Java

Featherweight Java (FJ) [14] is a minimal core calculus of the Java language, proposed by Igarashi et. al. There are many models built on Featherweight Java, including Feather-Trait [16], Featherweight defenders [12], Jx [21], Featherweight Scala [8], and so on. FJ provides the standard model of formalizing Java-like object-oriented languages and is easily extensible. In terms of formalization, the key novelty of our model is making use of various types (such as parameter types, method return types, etc) **YANLIN: fixed** to track the static types as well as the dynamic types during reduction. As far as we know, this technique has not appeared in the literature before. This notion is of vital importance in our hierarchical dispatch algorithm, and it allows for a more precise subject-reduction theorem as discussed in Section 3.

7 Conclusion

This paper proposes **FHJ** as a formalized multiple inheritance model for unintentional method conflicts. Previous approaches either do not support unintentional method conflicts, thus have to compromise between code reuse and type safety, or do not fully support overriding in the presence of unintentional conflicts. To deal with unintentional method conflicts we introduce two key mechanisms: hierarchical dispatching and hierarchical overriding. Hierarchical dispatching is inspired by the mechanisms in C++. We provide a minimal formal model of hierarchical dispatching in **FHJ**. Such an algorithm makes use of both dynamic type information and static information from either upcasts or parameters' information. It not only offers great code reuse like dynamic dispatch but also ensures unambiguity by our algorithm for method resolution. Additionally we introduce *hierarchical overriding* to allow conflicting methods in different branches to be individually overridden.

FHJ is formalized following the style of Featherweight Java and proved to be sound. A prototype interpreter is implemented in Scala. We believe that the formalization of hierarchical dispatching features is general and can be safely embedded in other OO models, so as to have support for the fork inheritance.

Our model can certainly be improved in some aspects. As discussed in Section 5, there are orthogonal and non-orthogonal features that can potentially be added to the design space. The future work relates to loosening the model without giving up its soundness, together with more exploration on supporting fields in the multiple inheritance setting.

A Appendix

A.1 Proofs

► **Lemma 5.** *If $\text{mbody}(\mathbf{m}, I_d, I_s) = (J, \overline{I_x} \ \overline{x}, I_e \ e_0)$, then $\overline{x} : \overline{I_x}, \text{this} : J \vdash e_0 : I_0$ for some $I_0 <: I_e$.*

Proof. By the definition of mbody , the target method \mathbf{m} is found in J . By the method typing rule (T-METHOD), there exists some $I_0 <: I_e$ such that $\overline{x} : \overline{I_x}, \text{this} : J \vdash e_0 : I_0$. ◀

► **Lemma 6** (Weakening). *If $\Gamma \vdash e : I$, then $\Gamma, x : J \vdash e : I$.*

Proof. Straightforward induction. ◀

► **Lemma 7** (Method Type Preservation). *If $\text{mbody}(\mathbf{m}, J, J) = (K, \overline{I_x} \ _, I_e \ _)$, then for any $I <: J$, $\text{mbody}(\mathbf{m}, I, J) = (K', \overline{I_x} \ _, I_e \ _)$.*

Proof. Since $\text{mbody}(\mathbf{m}, J, J)$ is defined, by (T-INTF) we derive that $\text{mbody}(\mathbf{m}, I, J)$ is also defined. Suppose that

$$\begin{aligned} \text{findOrigin}(\mathbf{m}, J, J) &= \{I_0\} \\ \text{findOverride}(\mathbf{m}, J, I_0) &= \{K\} \\ \text{findOrigin}(\mathbf{m}, I, J) &= \{I'_0\} \\ \text{findOverride}(\mathbf{m}, I, I'_0) &= \{K'\} \end{aligned}$$

Below we use $I[\mathbf{m} \uparrow J]$ to denote the type of method \mathbf{m} defined in I that overrides J . We have to prove that $K'[\mathbf{m} \uparrow I'_0] = K[\mathbf{m} \uparrow I_0]$. Two facts:

- A. By (T-INTF), canOverride ensures that an override between any two original methods preserves the method type. Formally,

$$I_1 <: I_2 \Rightarrow I_1[\mathbf{m} \uparrow I_1] = I_2[\mathbf{m} \uparrow I_2]$$

- B. By (T-METHOD) and (T-ABSMETHOD), any partial override also preserves method type. Formally,

$$I_1 <: I_2 \Rightarrow I_1[\mathbf{m} \uparrow I_2] = I_2[\mathbf{m} \uparrow I_2]$$

By definition of findOverride , $K <: I_0, K' <: I'_0$. By Fact B,

$$K[\mathbf{m} \uparrow I_0] = I_0[\mathbf{m} \uparrow I_0] \quad K'[\mathbf{m} \uparrow I'_0] = I'_0[\mathbf{m} \uparrow I'_0]$$

Hence it suffices to prove that $I'_0[\mathbf{m} \uparrow I'_0] = I_0[\mathbf{m} \uparrow I_0]$. Actually when calculating $\text{findOrigin}(\mathbf{m}, J, J)$, by the definition of findOrigin we know that $I_0 <: J$ and $I_0[\mathbf{m} \text{ override } I_0]$ is defined. So when calculating $\text{findOrigin}(\mathbf{m}, I, J)$ with $I <: J$, I_0 should also appear in the set before pruned, since the conditions are again satisfied. But after pruning, only I'_0 is obtained, by definition of prune it implies $I'_0 <: I_0$. By Fact A, the proof is done. ◀

► **Lemma 8** (Term Substitution Preserves Typing). *If $\Gamma, \overline{x} : \overline{I_x} \vdash e : I$, and $\Gamma \vdash \overline{y} : \overline{I_x}$, then $\Gamma \vdash [\overline{y}/\overline{x}]e : I$.*

Proof. We prove by induction. The expression e has the following cases:

Case Var. Let $e = x$. If $x \notin \bar{x}$, then the substitution does not change anything.

Otherwise, since \bar{y} have the same types as \bar{x} , it immediately finishes the case.

Case Invk. Let $e = e_0.m(\bar{e})$. By (T-INVK) we can suppose that

$$\begin{aligned} \Gamma, \bar{x} : \bar{I}_x \vdash e_0 : I_0 \quad \text{mbody}(m, I_0, I_0) = (_, \bar{J} _, I _) \\ \Gamma, \bar{x} : \bar{I}_x \vdash \bar{e} : \bar{I}_e \quad \bar{I}_e <: \bar{J} \quad \Gamma, \bar{x} : \bar{I}_x \vdash e : I \end{aligned}$$

By induction hypothesis,

$$\Gamma \vdash [\bar{y}/\bar{x}]e_0 : I_0 \quad \Gamma \vdash [\bar{y}/\bar{x}]\bar{e} : \bar{I}_e$$

Again by (T-INVK), $\Gamma \vdash [\bar{y}/\bar{x}]e : I$.

Case New. Straightforward.

Case Anno. Straightforward by induction hypothesis and (T-ANNO). ◀

A.1.1 Proof for Theorem 1

Proof.

Case S-Invk. Let

$$\begin{aligned} e &= ((J)\text{new } I()).m(\bar{v}) \quad \Gamma \vdash e : I_e \\ e' &= (I_{e_0})[(\bar{I}_x)\bar{v}/\bar{x}, (I_0)\text{new } I()/\text{this}]e_0 \\ \text{mbody}(m, I, J) &= (I_0, \bar{I}_x \bar{x}, I_{e_0} e_0) \end{aligned}$$

Since $\text{mbody}(m, I, J)$ is defined, the definition of mbody ensures that $I <: J$. And since e is well-typed, by (T-INVK),

$$\Gamma \vdash \bar{v} : \bar{I}_v \quad \bar{I}_v <: \bar{I}_x$$

By the rules (T-ANNO) and (T-NEW),

$$\Gamma \vdash (\bar{I}_x)\bar{v} : \bar{I}_x \quad \Gamma \vdash (I_0)\text{new } I() : I_0$$

On the other hand, by Lemma 5,

$$\bar{x} : \bar{I}_x, \text{this} : I_0 \vdash e_0 : I'_{e_0} \quad I'_{e_0} <: I_{e_0}$$

By Lemma 6,

$$\Gamma, \bar{x} : \bar{I}_x, \text{this} : I_0 \vdash e_0 : I'_{e_0}$$

Hence by Lemma 8, the substitution preserves typing, thus

$$\Gamma \vdash [(\bar{I}_x)\bar{v}/\bar{x}, (I_0)\text{new } I()/\text{this}]e_0 : I'_{e_0}$$

Since $I'_{e_0} <: I_{e_0}$, the conditions of (T-ANNO) are satisfied, hence $\Gamma \vdash e' : I_{e_0}$. Now we only need to prove that $I_{e_0} = I_e$. Since I_{e_0} is from $\text{mbody}(m, I, J)$, whereas I_e is from $\text{mbody}(m, J, J)$, by the rule (T-INVK) on e . Since $I <: J$, by Lemma 7, $I_{e_0} = I_e$.

Case C-Receiver. Straightforward induction.

Case C-Args. Straightforward induction.

Case C-StaticType. Immediate by (T-ANNO).

Case C-FReduce. Immediate by (T-ANNO) and induction.

Case C-AnnoReduce. Immediate by (T-ANNO) and transitivity of $<:$. ◀

A.1.2 Proof for Theorem 2

Proof. Since e is well-typed, by (T-INVK) and (T-ANNO) we know that

$$I <: J, \text{ and } \text{mbody}(m, J, J) \text{ is defined}$$

By (T-INTF), $\text{mbody}(m, I, J)$ is also defined, and the type checker ensures the expected number of arguments.

On the other hand, since $I <: J$, by the definition of `findOrigin`,

$$\text{findOrigin}(m, I, J) \subseteq \text{findOrigin}(m, I, I)$$

By (T-NEW), $\text{canInstantiate}(I) = \text{True}$. By the definition of `canInstantiate`, any $J_0 \in \text{findOrigin}(m, I, I)$ satisfies that $\text{findOverride}(m, I, J_0)$ contains only one interface, in which the m that overrides J_0 is a concrete method. Therefore $\text{mbody}(m, I, J)$ also provides a concrete method, which finishes the proof. ◀

A.1.3 Proof for Theorem 4

Proof. The Proof is done by induction on a derivation of $t \rightarrow t'$, following the book *TAPL*.

- If the last rule used in the derivation of $t \rightarrow t'$ is (S-INVK), then we know that t has the form $((J)\text{new } I()) \cdot m(\bar{v})$ with I, J, m determined. Now it is obvious that the last rule in the derivation of $t \rightarrow t''$ should also be (S-INVK) with the same I, J, m . Since $\text{mbody}(m, I, J)$ is a *function* that given the same input will calculate the same result, we know the two induction results are the same, thus $t' = t''$ is immediately proved.
- If the last rule used in the derivation of $t \rightarrow t'$ is (C-RECEIVER), then t has the form $e_0 \cdot m(\bar{e})$ and $e_0 \rightarrow e'_0$. Since e_0 is not a value, the last rule used in $t \rightarrow t''$ has to be (C-RECEIVER) (other rules do not match) too. Assume in the reduction $t \rightarrow t''$, $e_0 \rightarrow e''_0$, thus $e'_0 \cdot m(\bar{e}) = e''_0 \cdot m(\bar{e})$. Thus, $t' = t''$ proved.
- If the last rule used in the derivation of $t \rightarrow t'$ is (C-STATIC TYPE), then t is fixed to be `new I()`. The last rule used in $t \rightarrow t''$ has to be (C-STATIC TYPE), and obviously, $t' = t'' = (I)\text{new } I()$.
- If the last rule used in the derivation of $t \rightarrow t'$ is (C-FREDUCE), then t has the form $(I)e$ and $e \rightarrow e'$. The last rule used in $t \rightarrow t''$ cannot be (C-STATIC TYPE) because it requires t to be `new I()`; it can neither be (C-ANNOREDUCE) because it requires t to be $(I)((J)\text{new } K())$ where $(J)\text{new } K()$ is already a value. So the last rule used in $t \rightarrow t''$ can only be (C-FREDUCE) (other rules do not match). Assume in the reduction $t \rightarrow t''$, $e \rightarrow e''$, and $(I)e \rightarrow (I)e''$. By induction hypothesis, $e' = e''$, thus $t' = t''$ proved.
- If the last rule used in the derivation of $t \rightarrow t'$ is (C-ANNOREDUCE), then the form of t is fixed to be $(I)((J)\text{new } K())$. Since $(I)((J)\text{new } K())$ is not reducible, the rule (C-FREDUCE) does not apply. The only rule applies in $t \rightarrow t''$ is (C-ANNOREDUCE). Thus $t' = t'' = (I)\text{new } K()$ proved.
- If the last rule used in the derivation of $t \rightarrow t'$ is (C-ARGS), then t has the form $v \cdot m(\dots, e, \dots)$ and $e \rightarrow e'$. The last rule used in $t \rightarrow t''$ cannot be (S-INVK) because it requires all arguments to be values. Thus only (C-ARGS) applies to $t \rightarrow t''$. Assume in the reduction $t \rightarrow t''$, $e \rightarrow e''$. By induction hypothesis, $e' = e''$, thus $v \cdot m(\dots, e', \dots) = v \cdot m(\dots, e'', \dots)$, thus $t' = t''$ proved.
